

Maximilien Richer, Deuxfleurs

`https://garagehq.deuxfleurs.fr/ Matrix channel: #garage:deuxfleurs.fr`

Our objective at Deuxfleurs

French association promoting digital sovereignty and privacy
through self-hosting hosting **as an alternative to large cloud providers**

This requires resilience

(we want good uptime/availability with low supervision)

But what is Garage, exactly?

Garage is a self-hosted drop-in replacement for the Amazon S3 object store that implements resilience through geographical redundancy on commodity hardware

What makes Garage different?

Coordination-free:

- ▶ No Raft or Paxos
- ▶ Internal data types are CRDTs
- ▶ All nodes are equivalent (no master/leader/index node)

→ less sensitive to higher latencies between nodes

What makes Garage different?

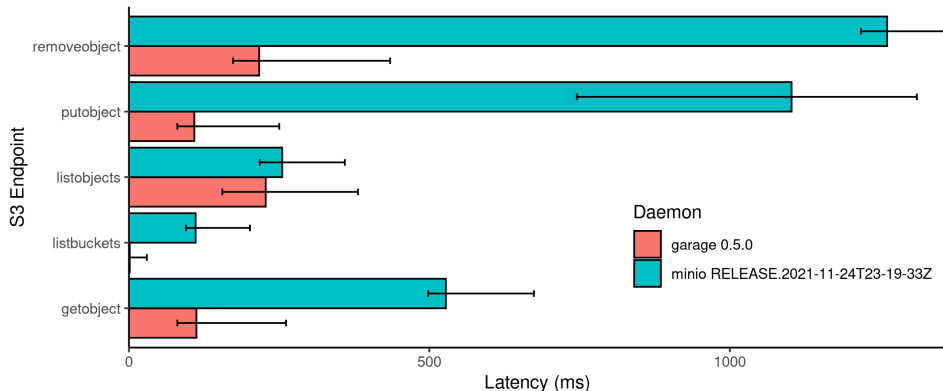

TODO update with latest garage and minio versions

S3 endpoint latency in a simulated geo-distributed cluster

100 measurements, 6 nodes in 3 DC (2 nodes/DC), 100ms RTT + 20ms jitter between DC

no contention: latency is due to intra-cluster communications

colored bar = mean latency, error bar = min and max latency

Get the code to reproduce this graph at <https://git.deuxfleurs.fr/quentin/benchmarks>

What makes Garage different?

Consistency model:

- ▶ Not ACID (not required by S3 spec) / not linearizable
- ▶ **Read-after-write consistency**
(stronger than eventual consistency)

What makes Garage different?

Location-aware:

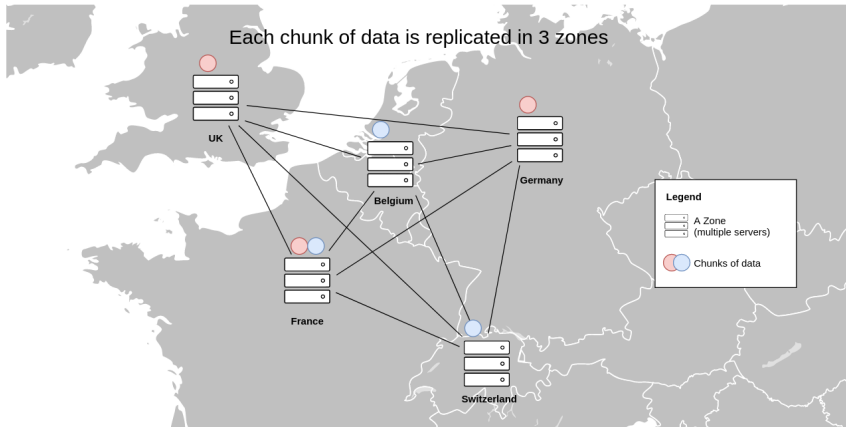

```
alex@io:~$ docker exec -ti garage /garage status
==== HEALTHY NODES ====
```

ID	Hostname	Address	Tags	Zone	Capacity
d9b5959e58a3ab8c...	drosera	[2a01:e0a:260:b5b0::4]:3901	[drosera,atuin]	atuin	20
156d0f7a88b1e328...	digitale	[2a01:e0a:260:b5b0::3]:3901	[digitale,atuin]	atuin	10
966dfc7ed8049744...	datura	[2a01:e0a:260:b5b0::2]:3901	[datura,atuin]	atuin	10
7d50f042280fea98...	io	[2a01:e0a:5e4:1d0::57]:3901	[io,jupiter]	jupiter	20

```
alex@io:~$
```

Garage replicates data on different zones when possible

What makes Garage different?

An ever-increasing compatibility list

Garage

Version history and roadmap

- ▶ v0.3: initial beta release (2021)
- ▶ v0.7: first released version (2022)
- ▶ v1.0: stable release (2024), will be deprecated in summer 2026 1y after v2.0 was released
- ▶ v2.0: stable release (2025)
 - ▶ new HTTP admin API
 - ▶ reworded replication configuration: `replication_mode` changed to `replication_factor` & `consistency_policy`
- ▶
v3.0: TBA may include versioning support, tag on buckets and objects, retention policies...

Best practices for Garage deployments

Things you should know

- ▶ no TLS support, use your own proxy
- ▶ no anonymous access (use website endpoint)
- ▶ you need to assign roles to nodes manually
- ▶ the replication factor cannot be changed easily
- ▶ the default region is garage and not us-east-1
- ▶ only use the degraded consistency policy for data recovery!

What hardware should I use?

- ▶ do NOT use network file storage (NFS, SMB, etc.) for metadata
- ▶ get a **write-intensive flash disk** for the metadata folder
- ▶ set it up as a RAID1 if possible, with a COW filesystem (e.g. Btrfs or ZFS)
- ▶ get large HDDs for the data folder
- ▶ use XFS and garage multi-hdd mode for best performance
- ▶ you can use a RAID for data but you'll leave a lot of performance on the table

Garage doesn't require a powerful CPUs nor much RAM, but your performance will depend on your disks!

Picking a metadata engine

All files-to-block mappings are stored in the metadata engine, including bucket and object metadata. Files below 3KB are stored directly in the metadata engine.

- ▶ Sled: removed in 1.x, move to SQLite or LMDB
- ▶ **SQLite**: safer, **recommended for small clusters and single-node**
- ▶ LMDB: faster, recommended for large clusters with metadata redundancy
 - ▶ Warning: limited to 480 bytes per key with LMDB (not an issue in practice)
- ▶ Fjall: experimental but promising rust-native engine, test it and let us know!

Metadata engine can be set node per node, and changed later with a migration tool

Single-node deployment

- ▶ garage was initially designed for multi-node deployments
- ▶ single-node deployments are possible, but you will lose resilience
- ▶ **If you do please ensure you have backups** (especially for metadata)
 - ▶ set up `metadata_auto_snapshot_interval`
- ▶ use sqlite to minimize data loss risks on powercuts
- ▶ or use a UPS!

Use github.com/bikeshedder/garage-single-node for an easy single-node setup!

Multi-node deployment

- ▶ try to have geo-distributed zones
- ▶ multiple nodes per zone to add more capacity
- ▶ at least 3 zones for best resilience
- ▶ keep in mind your available network and IO bandwidth
- ▶ **Rebalancing a cluster can take multiple weeks with large HDDs and slow network links**
- ▶ monitor your nodes with Prometheus + Grafana

Deuxfleurs has been running a 9TB (3TB usable) 8-nodes cluster (3+3+2) over retail fiber (10ms site-to-site latency) for close to 5 years now. We heard there are petabyte clusters out there!

Deploying and administering garage at scale

- ▶ deploy with your favorite tool (eg. Ansible) and system manager (eg. systemd)
- ▶ or use Docker, docker-compose, Kubernetes or Nomad
- ▶ Kubernetes and Consul are supported for node-to-node discovery
 - ▶ you'll still have to manage the layout manually!
- ▶ use gateway nodes to optimize network usage
- ▶ adjust `resync-tranquility` and `scrub-tranquility` to your resources

How to make sense of garage metrics?

What if things go wrong?

- ▶ set logs to debug with
`RUST_LOG=garage_api_common=debug,garage_api_s3=debug,garage=debug`
- ▶ auth issues: check your reverse proxy configuration
- ▶ slow resync: check your network and disk IO usage, and `resync-tranquility` worker configuration
- ▶ big LMDB database: stop garage and compact with `mdb_copy -c`
- ▶ ask us on matrix `#garage:deuxfleurs.fr` or open an issue on `git.deuxfleurs.fr`!
 - ▶ provide the output of `garage status`, `garage stats` and relevant metrics and log excerpts

Demo time!
